

Lecture XI: Topological Chirality

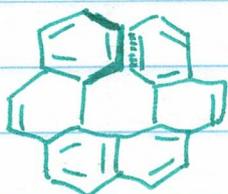

02-07-2020

Before we get into it, we will look at two examples of molecules which do not have a plane or axis, at least not a clearly distinguished one.

Helicenes

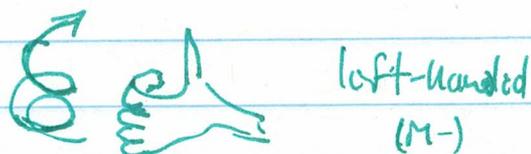

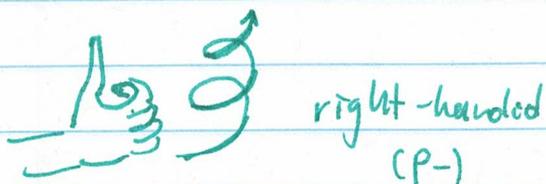

1947 - these three rings can no longer be coplanar

[6] helicene JACS, 1956, 78, 4765

Since then, helicenes with as many as 14 rings have been made. They are named as P- or M- if they describe a right or left-handed helix respectively:

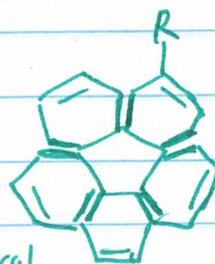

Helicenes are the closest to axially chiral compounds

Substituted corannulenes

bowl-shaped

single substituent makes it chiral

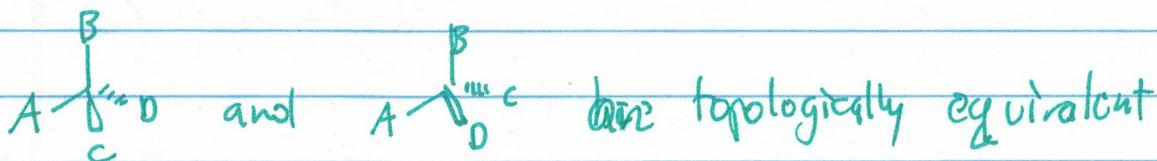

# Topological Chirality

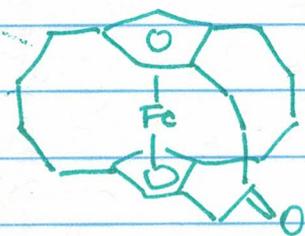

based mostly on Chem Soc Rev  
2018, 47, 5266

What is molecule's topology?

It is simply its connectivity. Bonds and atoms can be stretched and turned but not made to cross each other.

But some molecules are chiral as a consequence of their topology:

J. Organomet. Chem. 1977, 125, 79  
remains chiral regardless of substitution

This type of chirality is quite common in mechanically interlocked molecules - rotaxanes and catenanes (MIMs)

[2]rotaxane

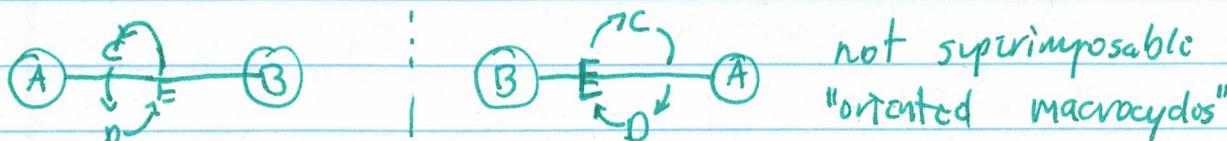

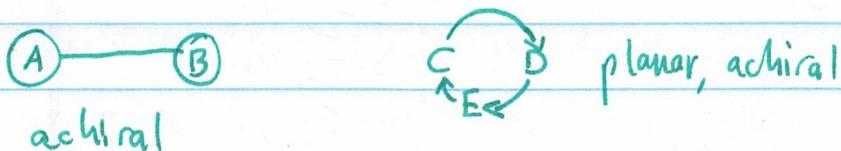

[2]catenane

two components which are not chemically connected but are still inseparable

they have a "mechanical bond"

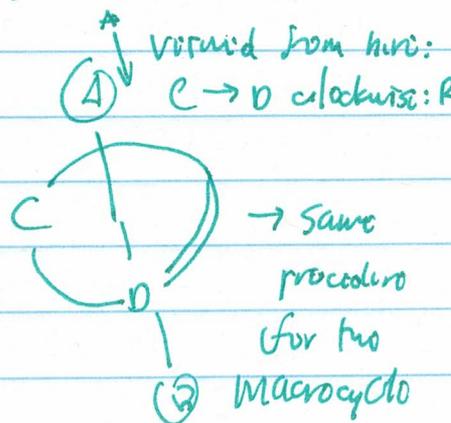

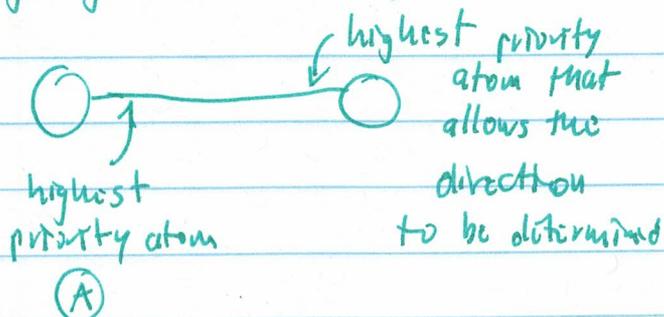

Rotaxanes composed of a  $C_{nh}$ -symmetric macrocycle and a  $C_{nv}$ -symmetric axle are going to be chiral - even though

neither one of their elements is chiral:

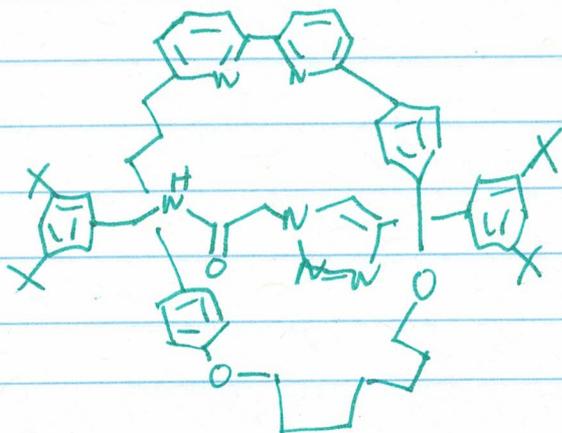

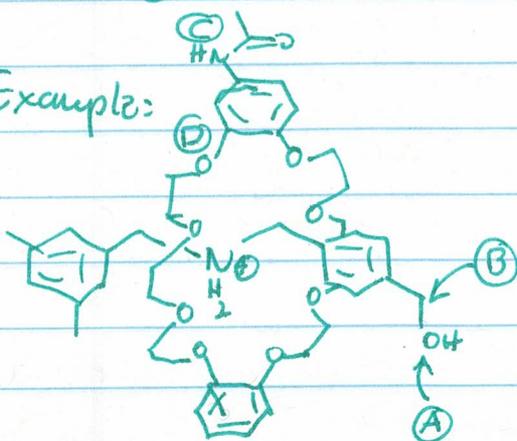

This can be viewed as a form of planar chirality. Macrocycle is the plane, which has been desymmetrized by the introduction of the axle.

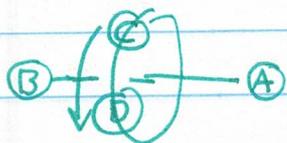

Assigning R/S configuration:

Example:

Goldup

(S)-configuration

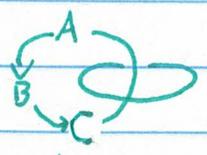

# Topologically Chiral Catenanes

Both rings need to be oriented:

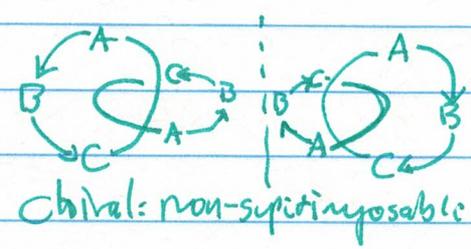

this is truly topological chirality!

achiral

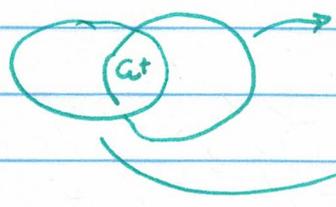

achiral

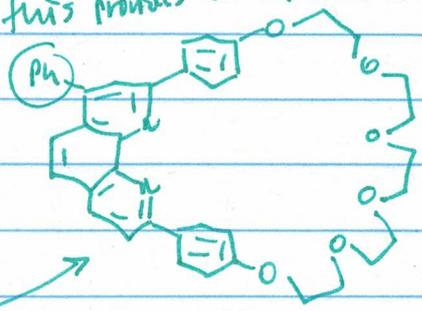

chiral: non-superimposable

Enantiomers have been separated, but their stereochemistry was not assigned.

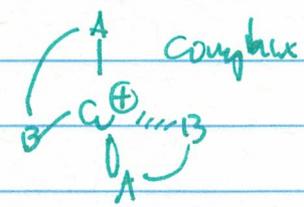

Example

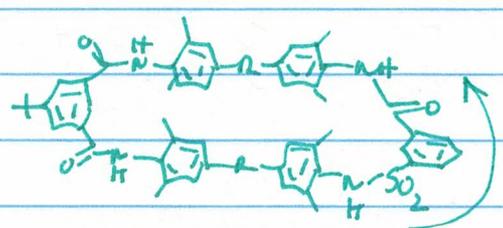

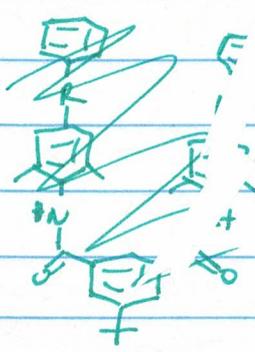

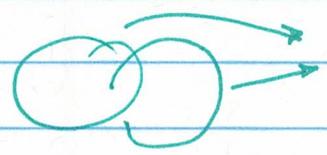

this provides an orientation

This can technically be viewed as a

Examples without a metal center:

directionality introduced

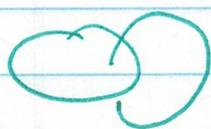

Other, more complex mechanically interlocked molecules can also be chiral:

JACS, 2015, 137, 10437

trefoil knot - inherently chiral

In addition, MIMs show right co-conformational behavior, in which the two components change their relationship to each other:

achiral

chiral

chiral

JACS 2007, 129, 2236

depending on  
the system, this  
process can be fast  
or slow
